## Abstract

**English.** We address the problem of recognition of medical entities in clinical records written in Italian. We report on experiments performed on medical data in English provided in the shared tasks at CLEF-ER 2013 and SemEval 2014. This allowed us to refine Named Entity recognition techniques to deal with the specifics of medical and clinical language in particular. We present two approaches for transferring the techniques to Italian. One solution relies on the creation of an Italian corpus of annotated clinical records and the other on adapting existing linguistic tools to the medical domain.

**Italiano.** *Questo lavoro affronta il problema del riconoscimento di entità mediche in referti medici in lingua italiana. Riferiamo su degli esperimenti svolti su testi medici in inglese forniti nei task di CLEF-ER 2013 e SemEval 2014. Questi ci hanno consentito di raffinare le tecniche di Named Entity recognition per trattare le specificità del linguaggio medico e in particolare quello dei referti clinici. Presentiamo due approcci al trasferimento di queste tecniche all'italiano. Una soluzione consiste nella creazione di un corpus di referti medici in italiano annotato con entità mediche e l'altro nell'adattare strumenti tradizionali per l'analisi linguistica al dominio medico.*

## 1 Introduction

One of the objectives of the *RIS* project (RIS 2014) is to develop tools and techniques to help identifying patients at risk of evolving their disease into a chronic condition. The study relies on a sample of patient data consisting of both medical test reports and clinical records. We are interested in verifying whether text analytics, i.e. in-

formation extracted from natural language texts, can supplement or improve information extracted from the more structured data available in the medical test records.

Clinical records are expressed as plain text in natural language and contain mentions of diseases or symptoms affecting a patient, whose accurate identification is crucial for any further text mining process.

Our task in the project is to provide a set of NLP tools for extracting automatically information from medical reports in Italian. We are facing the double challenge of adapting NLP tools to the medical domain and of handling documents in a language (Italian) for which there are few available linguistic resources.

Our approach to information extraction exploits both supervised machine-learning tools, which require annotated training corpora, and unsupervised deep learning techniques, in order to leverage unlabeled data.

For dealing with the lack of annotated Italian resources for the bio-medical domain, we attempted to create a silver corpus with a semi-automatic approach that uses both machine translation and dictionary based techniques. The corpus will be validated through crowdsourcing.

## 2 Medical Training Corpus

Currently Italian corpora annotated with mentions of medical terms are not easily available. Hence we decided to create a corpus of Italian medical reports (IMR), annotated with medical mentions and to make it available on demand.

The corpus consists of 10,000 sentences, extracted from a collection of 23,695 clinical records of various types, including discharge summaries, diagnoses, and medical test reports.

The annotation process consists in two steps: creating a silver corpus using automated tools

and then turning the corpus into a gold one by manually correcting the annotations.

For building the silver corpus we used:

- a NER trained over a silver English resource translated to Italian;
- a dictionary-based entity recognition approach.

For converting the silver corpus into a gold one, validation by medical experts is required. We organized a crowdsourcing campaign, for which we are recruiting volunteers to whom we will assign micro annotation tasks. Special care will be taken to collect answers reliably.

## 2.1 Translation based approach

The CLEF-ER 2013 challenge (Rebholz-Schuhmann et al., 2010) aimed at the identification of mentions in bio-medical texts in various languages, starting from an annotated resource in English, and at assigning to them a concept unique identifier (CUI) from the UMLS thesaurus (Bodenreider, 2004). UMLS combines several multilingual medical resources, including Italian terminology from MedDRA Italian (MDRITA15\_1) and MESH Italian (MSHITA2013), bridged through their CUI's to their English counterparts.

The organizers provided a silver standard corpus (SSC) in English, consisting of 364,005 sentences extracted from the EMEA corpus, which had been automatically annotated by combining the outputs of several Named Entity taggers (Rebholz-Schuhmann et al., 2010).

In (Attardi et al., 2013) we proposed a solution for annotating Spanish bio-medical texts, starting from the SSC English resource. Our approach combined techniques of machine translation and NER and consists of the following steps:

1. phrase-based statistical machine translation is applied to the SSC in order to obtain a corresponding annotated corpus in the target language. A mapping between mentions in the original and the corresponding ones in the translation is preserved, so that the CUIs from the original can be transferred to the translation. This produces a Bronze Standard Corpus (BSC) in the target language. A dictionary of entities is also created, which associates to each pair (entity text, semantic group) the corresponding CUIs that appeared in the SSC.
2. the BSC is used to train a model for a Named Entity tagger, capable of assigning semantic groups to mentions.
3. the model built at step 2) is used for tagging entities in sentences in the target language.

4. the annotated document is enriched by adding CUIs to each entity, looking up the pair (entity, group) in the dictionary of CUIs, of step 1.

For machine translation we trained Moses (Koehn, 2007) using a biomedical parallel corpus consisting of EMEA, Medline and the Spanish Wikipedia for the language model.

In task A of the challenge, on mention identification, our submission achieved the best score for the categories disease, anatomical part, live being and drugs, with scores ranging between 91.5% and 97.4% (Rebholz-Schuhmann et al., 2013). In task B on CUI identification, the scores were however much lower.

As NE tagger, we used the TanI NER (Attardi et al., 2009), a generic sequence tagger based on a Maximum Entropy Markov Model, that uses a rich feature set, customizable by providing a feature model. Such kinds of taggers perform quite well on newswire documents, where capitalization features are quite helpful in identifying people, organization and locations. With a proper feature model we were able to achieve satisfactory results also for medical domain.

Adapting the CLEF-ER approach to Italian required repeating the translation step with an English parallel corpus, consisting of EMEA and UMLS for the medical domain and (Europarl, 2014; JRC-Acquis, 2014) for more general domains.

A NE tagger for Italian was trained on the translated silver corpus.

Due to a lack of annotated Italian medical texts, we couldn't perform validation on the resulting tagger. Manual inspection confirms the hypothesis that accuracy is similar to the Spanish version, given that the major difference in the process is the translation corpus and that Spanish and Italian are similar languages.

## 2.2 Dictionary based approach

Since the terminology for entities in medical records is fairly restricted, another method for identifying mentions in the IMR corpus is to use a dictionary. We produced an Italian medical thesaurus by merging:

- over 70,000 definitions of treatments and diagnosis from the ICD-9-CM terminology;
- about 22,000 definitions from the SnoMed semantic group "Symptoms and Signs, Disease and Anatomical part" in the UMLS;
- over 2,600 active ingredients and drugs from the "Lista dei Farmaci" (AIFA, 2014).

We identified mentions in the IMR corpus using two techniques:  $n$ -gram based and parser based.

most NE taggers. The conversion is not straightforward since clinical reports contain discontinuous and overlapping mentions. For example, in:

```
Abdomen is soft, nontender, non-
distended, negative bruits
```

there are two mentions: Abdomen nontender and Abdomen bruits.

The IOB format does not allow either discontinuity or overlaps. We tested two conversions: one by replicating a sentence, each version having a single mention from a set of overlapping ones. The second approach consisted in using additional tags for disjoint and shared mentions (Tang et al., 2013): DISO for contiguous mentions; DDISO for disjoint entity words that are not shared by multiple mentions; HDISO for the head word that belongs to more than one disjoint mentions.

We tested the accuracy of various NE taggers on the SemEval development set. The results are reported in Table 1. Results marked with *discont* were obtained with the additional tags for discontinuous and overlapping mentions.

NER	Precision	Recall	F-score
Tanl	80.41	65.08	71.94
Tanl+dbscan	<b>80.43</b>	64.48	71.58
Tanl+word2vec	79.70	<b>67.44</b>	<b>73.06</b>
Nlpnet	80.29	62.51	70.29
Stanford	80.30	64.89	71.78
CRFsuite	79.69	61.97	69.72
Tanl discont	78.57	65.35	71.35
Nlpnet discont	77.37	63.76	69.61
Stanford discont	80.21	62.79	70.44

Table 1: Accuracy on the development set.

### 3.2 Semeval 2014 NER for clinical text

The task 7 of SemEval 2014 allowed us to test NE tagging techniques on medical records and to adapt them to the task. Peculiarly, only one class of entities, namely diseases, is present in the corpus.

We dealt with overlapping mentions by converting the annotations. Discontiguous mentions were dealt in two steps: the first step identifies contiguous portions of a mention with a traditional sequence labeler; then separate portions of mentions are combined into a full mention with guidance from a Maximum Entropy classifier (Berger et al., 1996), trained to recognize which pairs belong to the same mention. The training set consists of all pairs of terms within a document annotated as disorders. A positive instance

is created if the terms belong to the same mention, a negative one otherwise.

The classifier was trained using a binned distance feature and dictionary features, extracted for each pair of words in the training set.

For mapping entities to CUIs we applied fuzzy matching (Fraser, 2011) between the extracted mentions and the textual description of entities present in a set of UMLS disorders. The CUI from the match with highest score is chosen.

Our submission reached a comparable accuracy to the best ones based on a single system approach (Pradhan et al., 2014), with an F-score of 0.65 for Task A and 0.83 for Task A relaxed. For Task B and Task B relaxed the accuracies were 0.46 and 0.70 respectively. Better results were achieved by submissions that used an ensemble of taggers.

We also attempted combinations of the outputs from the Tanl NER (with word2vec cluster features), Nlpnet NER and Stanford NER in several ways. The best results were obtained by a simple one voting approach, taking the union of all annotations. The results of the evaluation, for both the multiple copies and discount annotation style, are shown below:

NER	Precision	Recall	F-score
Agreement multiple	73.96	<b>73.68</b>	<b>73.82</b>
Agreement discont	<b>81.69</b>	65.85	72.92

Table 2: Accuracy of NER system combination.

## 4 Conclusions

We presented a series of experiments on biomedical texts from both medical literature and clinical records, in multiple languages, that helped us to refine the techniques of NE recognition and to adapt them to Italian. We explored supervised techniques as well as unsupervised ones, in the form of word embeddings or word clusters. We also developed a Deep Learning NE tagger that exploits embeddings. The best results were achieved by using a MEMM sequence labeler using clusters as features improved in an ensemble combination with other NE taggers.

As a further contribution of our work, we produced, by exploiting semi-automated techniques, an Italian corpus of medical records, annotated with mentions of medical terms.
